

Architecting the Zero-Loss Conversion Funnel: A Production Blueprint for a Custom-Built Nigerian PropTech Platform

Strategic Framework: Defining the Buyer/Renter Funnel and Core Business Logic

The foundational objective of this project is to architect a multi-faceted digital sales engine, not merely a property search website. This strategic distinction dictates that every element of the platform, from user interface to database schema, must be designed to capture high-intent user behavior and convert it into qualified sales leads. The model draws direct inspiration from successful market precedents such as Zillow's 'Make Me Move' feature, which effectively captured seller intent by offering future valuation alerts, and Compass's Concierge program, which provided pre-listing services in exchange for exclusive agency representation. Adapting these concepts for the Nigerian buyer and renter context requires a meticulously defined funnel that transforms moments of user frustration—specifically, the discovery that a desired property is unavailable—into opportunities for premium service engagement. The core business logic hinges on a conditional pivot: when a standard search yields no results, the user is presented with an offer to join a "2-Week Wait Concierge Search," a white-glove service promising to source the specific property they seek [84](#) [103](#). This conversion mechanism is the central pillar of the platform's lead generation strategy and must be codified with absolute precision during the discovery phase. The success of this funnel is predicated on its ability to function as a seamless, frictionless process that guides the user from an unmet need to a registered, high-priority lead, all while enforcing a strict two-hour Service Level Agreement (SLA) for follow-up by the internal sales team [74](#) [99](#).

To achieve this, the discovery workflow must begin with a deep understanding of the target persona and their journey. The ideal user is not a passive browser but an individual actively seeking a solution to a specific problem, characterized by a high degree of intent and a willingness to engage with a premium service to save time and effort. A representative persona for this initiative would be "Chinedu, 32, a tech professional," whose primary motivations include efficiency, trust in digital processes, and a preference for personalized service over repetitive manual tasks like calling agents

for properties that have already been sold ¹⁹. His pain points are well-defined: the frustration of seeing a desirable listing marked as "sold" or "unavailable" online, the inefficiency of manually sifting through multiple listings, and the desire for a guaranteed outcome within a predictable timeframe. The journey map for this persona documents every potential interaction with the platform, from the initial landing page to the final submission of the concierge registration form ¹⁵. It identifies critical touchpoints and potential drop-off points, such as the moment of encountering an unavailable listing. At this precise juncture, the user experience must pivot from one of failure ("No results found") to one of opportunity ("Unlock our Off-Market Concierge Search"). The language used in this transition is crucial; framing it as a premium, exclusive access rather than a dead end significantly increases the likelihood of user registration and commitment ⁸⁴. Every element of the UI at this stage, from button copy to form fields, must be optimized to communicate value and build trust, aligning with the persona's desire for a reliable and efficient solution ¹².

The operational heart of this strategic framework is the internal CRM, which will be built as a custom module on top of PostgreSQL, eliminating any dependency on external SaaS providers like HubSpot or Salesforce [assistant response]. This self-contained architecture ensures complete control over data, security, and the implementation of business logic. The CRM's primary function is to manage the lifecycle of each lead generated through the funnel, with a particular focus on enforcing the 2-hour SLA for concierge requests. Upon submission of the concierge form, the backend system must automatically create a record in the `concierge_leads` table with a `priority` flag set to `HIGH` ⁴³. This flag should immediately trigger an internal alert system, notifying the sales dashboard and ensuring the lead is assigned to an agent within the stipulated two hours ⁶⁸. The CRM must also incorporate a lead scoring mechanism, detailed in the database specifications, which assigns a numerical score based on factors like budget, location specificity, and responsiveness, allowing the sales team to prioritize outreach efforts effectively ⁴⁷. The entire system—from the frontend user interface to the backend processing and CRM management—is designed around this single, powerful conversion event, making the definition of its rules and triggers the most critical task of Phase 0. By establishing a rigid, unambiguous set of business rules before any design or code is written, the project mitigates the risk of scope creep, ensures alignment between business and technical teams, and lays a robust foundation for a scalable and compliant digital asset ^{56 101}.

Component	Description	Business Purpose
Persona Profile	A detailed psychological and behavioral profile of the target user, e.g., "Chinedu, 32, tech professional." Defines motivations, frustrations, and preferred communication channels.	To guide UX/UI design, microcopy, and overall marketing messaging to resonate with the target audience's specific needs and mindset.
User Journey Map	A visual and narrative representation of the user's path through the platform, highlighting every step, emotion, and potential point of friction or drop-off.	To identify critical decision points, optimize the flow for maximum conversion, and anticipate user needs throughout the experience.
Funnel Logic Specification	A formal document detailing the exact rules governing user flow, especially the conditional trigger for the concierge offer. Written in pseudo-code or strict business logic.	To provide developers with an unambiguous blueprint for implementing the core conversion engine, preventing guesswork and ensuring consistency.
SLA Enforcement Mechanism	A backend process that automatically flags high-priority concierge leads and triggers an internal alert to the sales dashboard, creating a clear accountability loop.	To guarantee a two-hour response time for premium leads, directly fulfilling the promise of the concierge service and enhancing customer satisfaction.
Lead Scoring Engine	A component of the internal CRM that assigns a score to each concierge lead based on predefined criteria (e.g., budget, location specificity).	To enable the sales team to prioritize outreach, focusing first on the highest-quality and most motivated leads to maximize conversion rates.

Data Architecture Specification: PostgreSQL Schema Design for a Self-Hosted CRM

The architectural cornerstone of this project is the creation of a fully custom, self-hosted Customer Relationship Management (CRM) system built upon a PostgreSQL database . This approach provides unparalleled control over data governance, security, and business logic, but it necessitates a rigorous and deliberate database schema design during the discovery phase. The database will serve as the single source of truth for all lead-related data, capturing everything from user consent to property search parameters and lead prioritization status. A comprehensive Entity-Relationship Diagram (ERD) must be produced and signed off before any development work commences, defining the structure of key tables, their columns, data types, constraints, and relationships [43](#) [105](#). This proactive schema design prevents the common pitfall of building frontend forms that do not align with the backend data structure, a misalignment that can lead to costly rework and data integrity issues later in the project [6](#) . The specified tables—`users`, `properties`, `concierge_leads`, `consent_logs`, and `lead_scores`—form the core of this data architecture, each serving a distinct and critical function in the lead generation and management lifecycle.

The `concierge_leads` table is the central repository for all data collected from users who opt into the premium service. It is designed to capture the full spectrum of information necessary for an agent to fulfill the two-week search commitment. Each field is carefully defined to ensure data quality and support downstream business processes like lead scoring and reporting. For example, `full_name`, `email`, and `phone` are essential for direct communication, while `target_location` and `max_budget` are critical parameters for the search itself. The inclusion of `property_specs_jsonb` allows for flexible storage of detailed property requirements that may not fit into predefined columns, accommodating nuanced user requests. Crucially, the table includes `status` and `priority` fields. The `status` field will track the lead's progression through the sales funnel (e.g., 'new', 'contacted', 'assigned', 'converted'), while the `priority` field, set to 'HIGH' for concierge submissions, is the mechanism for enforcing the 2-hour SLA ⁶⁸. This table's design reflects a deep understanding of the sales process, moving beyond simple contact management to intelligent automation and real-time tracking ²⁹.

The `consent_logs` table is a dedicated audit trail for all data processing activities, a non-negotiable requirement for GDPR compliance ¹⁴. Its existence ensures that the company can prove a lawful basis for processing personal data, placing the burden of proof squarely on the Data Controller ¹⁰¹. This table must be linked to the `concierge_leads` table via a foreign key, creating a permanent, timestamped record of every user's consent. Key columns include `is_consent_given` (a boolean), `consent_timestamp` (to log precisely when consent was granted), and `policy_version` (to indicate which version of the privacy policy the user agreed to) ¹⁵. This level of detail is essential for passing a regulatory audit. The table also serves as the foundation for managing the right to withdraw consent, a fundamental right under the NDPA ¹⁶. When a user requests to withdraw consent, the system can query this table to identify all associated data and initiate the appropriate rectification or erasure process. The design of this table exemplifies the principle of "data protection by design," where privacy controls are embedded directly into the database structure from the outset ⁵⁶.

Finally, the `lead_scores` table implements a dynamic lead scoring system, a critical tool for optimizing sales team efficiency. This table would typically store the scoring rules themselves (e.g., `IF budget > 50000000 THEN add 10 points`) and potentially a history of score changes for each lead. The scores calculated against the data in `concierge_leads` allow the sales team to triage incoming requests, focusing immediate attention on leads that match their ideal customer profile most closely. This moves the sales process from reactive to proactive, ensuring that resources are allocated to the opportunities with the highest probability of conversion. The combination of these

three tables (`concierge_leads`, `consent_logs`, `lead_scores`) creates a robust, compliant, and operationally effective CRM backbone that is entirely self-contained and tailored to the specific needs of the business. The other tables, `users` and `properties`, provide the foundational data for the main search functionality, completing the data architecture required for the buyer/renter portal.

Table Name	Column Name	Data Type	Constraints	Description
concierge_leads	id	UUID	PRIMARY KEY	Unique identifier for the concierge lead record.
	full_name	VARCHAR(100)	NOT NULL	The lead's full name.
	email	VARCHAR(255)	NOT NULL, UNIQUE	The lead's email address, used as a primary contact identifier.
	phone	VARCHAR(20)	NOT NULL	The lead's phone number.
	target_location	VARCHAR(100)	NOT NULL	The specific area or city the user is searching for.
	max_budget_ngn	INTEGER	NOT NULL	The maximum price the user is willing to pay, in Nigerian Naira.
	property_specs_jsonb	JSONB	NULL	Flexible storage for detailed property requirements (beds, baths, amenities, etc.).
	status	VARCHAR(20)	NOT NULL, DEFAULT 'new'	Current state of the lead in the sales funnel (e.g., new, contacted, assigned).
	priority	VARCHAR(10)	NOT NULL, DEFAULT 'normal'	Lead urgency; 'HIGH' for concierge requests to enforce SLA.
	created_at	TIMESTAMP	NOT NULL, DEFAULT NOW()	Timestamp of when the lead record was created.
consent_logs	id	UUID	PRIMARY KEY	Unique identifier for the consent record.
	lead_id	UUID	NOT NULL, REFERENCES concierge_leads(id)	Foreign key linking the consent to a specific lead.
	is_consent_given	BOOLEAN	NOT NULL	Record of whether explicit consent was granted.
	consent_timestamp	TIMESTAMP	NOT NULL	Precise timestamp of when consent was obtained.
	policy_version	VARCHAR(20)	NOT NULL	Version of the Privacy Policy the user agreed to.
	user_ip_address	INET	NULL	IP address of the user at the time of consent.
lead_scores	lead_id	UUID	PRIMARY KEY, REFERENCES concierge_leads(id)	Foreign key linking the score to a specific lead.
	score	INTEGER	NOT NULL, DEFAULT 0	Calculated score representing the lead's quality and potential.
	last_calculated	TIMESTAMP	NOT NULL, DEFAULT NOW()	Timestamp of the last time the score was updated.

Regulatory Compliance by Design: Embedding NDPR Requirements into System Architecture

In Nigeria, adherence to the Data Protection Act (NDPA) 2023 and its General Application and Implementation Directive (GAID) is not optional; it is a foundational requirement that must be woven into the very fabric of the system's architecture [11](#) [13](#). The GAID, which takes effect on September 19, 2025, replaces the older NDPR 2019 and establishes stringent standards for data processing [14](#) [25](#). Therefore, Phase 0 must produce a detailed NDPR Compliance Specification that translates legal obligations into concrete technical requirements. This involves more than just drafting a privacy policy; it requires designing and building features that actively demonstrate compliance, such as mechanisms for obtaining explicit consent, honoring data subject rights, and implementing a defensible data retention policy. Failure to embed these principles from the start exposes the organization to severe penalties, including fines up to ₦10 million or 2% of annual gross revenue, whichever is greater, alongside potential imprisonment for directors in serious cases [14](#) [16](#). The proposed workflow correctly identifies this by mandating the creation of specific backend endpoints and database structures dedicated to compliance, transforming a legal necessity into a core system capability [49](#).

The first and most critical compliance requirement is the establishment of a verifiable, explicit consent mechanism. Under the NDPA, free, informed, and explicit consent is a primary lawful basis for processing personal data [16](#). The system must implement this through a checked-by-default checkbox on the concierge registration form, accompanied by clear language stating the purpose of data processing (e.g., "I consent to [Company Name] processing my data to find a property for me, as outlined in the Privacy Policy") [15](#). The backend logic must block form submission if this checkbox is unchecked. Furthermore, the `consent_logs` table is the technical embodiment of this principle, capturing not only the user's choice but also an immutable timestamp, the version of the policy they agreed to, and their IP address [14](#). This creates an auditable trail that proves the consent was valid and informed, directly addressing the burden of proof placed on the Data Controller [101](#). This meticulous logging is a practical application of the principle of transparency, a core tenet of both NDPR and GDPR [14](#).

The second major compliance pillar is the implementation of data subject rights, specifically the Right of Access (the right to receive a copy of one's data) and the Right to Erasure ('right to be forgotten') [14](#) [90](#). The system architecture must include dedicated backend endpoints to handle these requests. An endpoint like `/api/user/data-export` must be developed to accept a user identifier (email or phone) and return all

associated personal data in a structured, commonly used format, such as JSON or CSV ¹⁵. Similarly, a secure admin endpoint, such as `/api/admin/user/hard-delete/{id}`, must be created to facilitate the complete deletion of a user's PII ⁶¹. It is crucial to understand that the "Right to Be Forgotten" is not absolute and must be balanced against other legal obligations ⁶. The system should therefore include a process for reviewing and approving or denying such requests based on predefined exemptions. However, the technical infrastructure to perform the deletion must be in place. The challenge of ensuring complete deletion across all backups and replicas must also be addressed, as simply deactivating an account while retaining the data is considered incomplete deletion and can lead to regulatory penalties ⁵ ⁶.

Finally, the data retention policy must be technically enforced. While the previous NDPR Implementation Framework suggested a three-year retention period for inactive data, the NDPA GAID introduces a stricter principle: data should not be kept longer than necessary to achieve the original purpose for which it was collected ¹⁴. In the context of a concierge lead, the original purpose might be fulfilled once the agent has made contact or the property is found, which could be much sooner than six months. The specification must define this retention period clearly. To enforce this, the system should leverage PostgreSQL's native capabilities, such as the `pg_cron` extension, to schedule a periodic job that automatically anonymizes or deletes records from the `concierge_leads` table that have exceeded their retention period and have no ongoing activity ⁶⁹ ⁷⁷. This automated process demonstrates a commitment to data minimization, another core principle of the NDPA, and reduces the risk of human error leading to non-compliance ¹⁴. The following table outlines the key NDPR requirements and their corresponding technical implementations within the proposed system architecture.

NDPR Requirement (from NDPA 2023/GAID)	Principle	Proposed Technical Implementation
Explicit Consent	Consent must be freely given, specific, informed, and unambiguous. 15 16	- Frontend: Checkbox with clear, affirmative action. - Backend: Block submission if checkbox is unchecked. - Database: <code>consent_logs</code> table with <code>is_consent_given</code>, <code>consent_timestamp</code>, <code>policy_version</code>.
Right of Access	Data subjects have the right to obtain confirmation and access to their personal data. 14 15	- Backend: Create <code>/api/user/data-export</code> endpoint to compile and deliver user data in JSON/CSV format.
Right to Erasure	Data subjects have the right to have their personal data erased under certain conditions. 14 90	- Backend: Create secure admin endpoint <code>/api/admin/user/hard-delete/{id}</code>. - Process: Implement a review/approval workflow before deletion.
Data Minimization	Personal data should be adequate, relevant, and limited to what is necessary. 14	- Database: Only collect fields explicitly needed for the stated purpose. - Process: Use <code>pg_cron</code> to automatically anonymize/delete old/inactive lead data.
Storage Limitation	Data should not be kept for longer than necessary for the purpose it was collected. 5 14	- Policy: Define retention period (e.g., 6 months post-purpose-fulfillment per GAID interpretation). - Automation: Schedule a PostgreSQL job to execute the data purging policy.
Accountability	The controller is responsible for and must be able to demonstrate compliance. 14 16	- Database: Maintain an immutable audit trail in <code>consent_logs</code> and change-tracking tables. - Documentation: The NDPR Compliance Specification document serves as a key artifact.

API Contract and Functional Logic: Specifying Search and Concierge Submission Endpoints

With the strategic framework and data architecture defined, the next critical step in Phase 0 is to formalize the API contract that will govern all interactions between the frontend application and the backend server. Since the system is being built as a custom, self-contained entity, there are no third-party APIs to rely on for core functionalities like property search or lead submission. Therefore, a precise and comprehensive specification of the RESTful endpoints is essential to ensure seamless integration and predictable behavior. These APIs will translate the business logic of the user journey into machine-readable instructions. The two most critical endpoints identified from the discovery process are `/api/search` for querying available properties and `/api/submit-concierge` for capturing high-intent leads from the fallback flow. The design of these endpoints must prioritize clarity, security, and performance, providing a stable interface for the frontend developers to build against.

The `/api/search` endpoint is the primary gateway for the standard buyer/renter experience. It must be designed to accept a flexible set of query parameters corresponding to the search filters a user would apply, such as location, property type, minimum and maximum number of bedrooms, and price range. The backend logic for this endpoint will translate these parameters into a SQL query against the `properties` table. To ensure optimal performance, particularly as the property database grows, the database must be properly indexed on frequently queried columns like `location`, `price`, and `property_type`. The API response must be standardized, returning a JSON object that contains the array of matching property objects, along with metadata about the search results, such as the total count of results and pagination information. This allows the frontend to efficiently render the property grid or list and display a user-friendly message if the result set is empty. The functional logic here is straightforward: execute the query, format the results, and return them. However, its importance cannot be overstated, as its reliability and speed directly impact the user's perception of the platform's quality.

The `/api/submit-concierge` endpoint is arguably the most strategically important API, as it is the entry point for the high-value lead conversion funnel. This endpoint is responsible for receiving the data submitted through the special registration form that appears when a search returns zero results. The payload sent to this endpoint will contain all the fields defined in the `concierge_leads` table, including personal information, target location, budget, and any additional property specifications. Server-side validation is paramount here to prevent malformed or malicious data from entering the database. The backend must validate the format of emails and phone numbers, ensure budget fields are numeric, and check for any unexpected or harmful content. Once the data passes validation, the system performs several critical actions in sequence. First, it inserts the lead's information into the `concierge_leads` table, automatically setting the `priority` field to 'HIGH'. Second, it creates a corresponding entry in the `consent_logs` table to securely record the user's explicit consent. Third, and most importantly, it triggers the internal SLA enforcement mechanism by sending a notification to the sales dashboard, thereby initiating the two-hour response timeline. The API's response to the frontend should be immediate and definitive, returning a success status upon completion of these steps, which will then redirect the user to a "thank you" page confirming their request has been received.

The functional logic that connects these two endpoints—the conditional trigger that redirects a user from a failed search to the concierge form—is a client-side responsibility handled by the frontend application. However, its implementation is dictated by the backend APIs. The frontend application, built with a framework like Next.js, will call the `/api/search` endpoint. Upon receiving the response, its logic will inspect the length of

the `results` array. If the length is zero, instead of displaying a generic "No results found" message, the frontend will render the specialized concierge offer UI. This UI will contain the `ConciergeForm`, which is configured to submit its data to the `/api/submit-concierge` endpoint. This tight coupling between the search API's output and the frontend's conditional rendering is the technical manifestation of the core business strategy. It transforms a negative user experience into a positive, value-added opportunity. The entire process, from search execution to lead submission and SLA triggering, is orchestrated through these well-defined API interactions, forming the operational backbone of the platform's lead generation engine.

Endpoint	HTTP Method	Request Body (JSON)	Successful Response (201 Created)	Error Responses (4xx/5xx)	Business Logic Summary
/api/search	GET	Query Parameters: location, min_price, max_price, property_type, beds, baths	json { "results": [{ / Property Object }], "metadata": { "total": 10, "page": 1, "limit": 20 } }	400 Bad Request (if required params missing) 500 Internal Server Error (if DB query fails)	Executes a parameterized SQL query against the <code>properties</code> table. Returns paginated results and metadata. Optimized with proper DB indexing.
/api/submit-concierge	POST	json { "full_name": "...", "email": "...", "phone": "...", "target_location": "...", "max_budget_ngn": 50000000, "property_specs_jsonb": { ... } }	201 Created json { "message": "Concierge request successfully submitted. An agent will contact you within 2 hours.", "lead_id": "uuid-guid" }	400 Bad Request (if data validation fails) 429 Too Many Requests (if rate limiting is triggered) 500 Internal Server Error (if DB insertion fails)	1. Validates incoming JSON data. 2. Inserts record into <code>concierge_leads</code> with <code>priority = 'HIGH'</code> . 3. Inserts consent record into <code>consent_logs</code> . 4. Triggers internal SLA alert to sales dashboard. Returns a success message and the new lead's ID.

Handoff Protocol and Project Governance: Establishing a Gatekeeper Workflow

The ultimate success of the discovery phase, and indeed the entire project, depends not only on the quality of the documents produced but also on the rigor of the handoff protocol that transitions the project from planning to execution. The proposed workflow establishes a gatekeeper system where no subsequent phase can begin until the preceding one has been formally approved by all key stakeholders. This disciplined approach is designed to eliminate ambiguity, prevent scope creep, and ensure that everyone involved—from Product Owner to Lead Developer to Legal Counsel—has a shared, unambiguous understanding of the project's direction before committing significant resources to development. The handoff from Phase 0 (Discovery Finalization) to Phases 1 (UX/UI Design) and 2 (Backend Architecture) is particularly critical, as it sets the tone for the entire build process. A poorly executed handoff can reintroduce the very ambiguities that the discovery phase was designed to resolve, leading to wasted effort, costly rework, and misaligned final products.

The formal handoff process consists of several key components designed to transfer knowledge effectively and confirm readiness. First is the **Handoff Meeting**, a mandatory, synchronous session involving the Product Owner, UX/UI Designer, Backend Lead, and QA Lead. During this meeting, the Product Owner acts as the primary facilitator, walking the group through the core deliverables of Phase 0: the finalized Product Requirements Document (PRD), the Entity-Relationship Diagram (ERD) for the database schema, the 1:1 CRM Field Mapping table, and the NDPR Compliance Specification. This is not a passive presentation; it is an interactive walkthrough designed to surface any questions, clarify assumptions, and ensure collective comprehension. The goal is to move from a document-based understanding to a shared mental model of the project's architecture and business logic.

Following the walkthrough, the process culminates in a "**Definition of Ready**" Check. This is a formal, verbal confirmation from the recipients of the handoff—the UX/UI Designer and the Backend Lead—that they possess all the necessary information to proceed with their respective phases without blocking dependencies. The Backend Lead must confirm that the database schema is sufficient to begin API development and that the API contract is clear. The UX/UI Designer must confirm that the PRD and field mapping provide enough detail to begin wireframing and that the conditional logic for the concierge offer is well-defined. This explicit confirmation creates a clear checkpoint and shifts ownership to the receiving team. If either party identifies a gap, the issue is documented and must be resolved before the gate is closed. This process institutionalizes

a culture of accountability and proactive problem-solving, preventing the classic "I thought you meant something else" scenario that plagues many software projects.

Once the handoff is complete, the final step is the **Repository and Documentation Setup**. The Backend Lead is responsible for creating the official Git repository for the project, initializing the codebase, and applying the database schema defined in the ERD. This early setup ensures that all development work is properly version-controlled from day one. Simultaneously, the Product Owner uploads the signed-off PRD and all associated Phase 0 documents to the central project management tool (e.g., Jira, Asana, or Linear), designating them as the master reference documents for the project ⁷². Any changes to the requirements after this point must go through a formal Change Request process, which is reviewed by the stakeholders before being incorporated. This formalizes the "single source of truth" principle, making the project's requirements transparent and immutable unless formally amended. This structured governance framework, from the initial discovery workshops to the final repository setup, provides a robust scaffold for building a complex, custom, and compliant system, ensuring that the final product is not only technically sound but also perfectly aligned with the strategic goals of the business.
